

Problem 1)

What are the lines of constant $u(x, y)$ and $v(x, y)$ for the function $f(z) = u(x, y) + iv(x, y) = \ln z$?

We can write

$$\ln z = \ln r + i\theta, \quad (1)$$

where we restrict $\theta \in [0, 2\pi)$ such that $\ln z$ is single-valued. Thus,

$$u(x, y) = \ln r \quad (2)$$

$$v(x, y) = \theta, \quad (3)$$

where $r = \sqrt{x^2 + y^2}$ and $\tan \theta = y/x$.

A plot of some of the lines of constant u and v are shown in Fig. 1

Figure 1:

Problem 2)

Calculate the integral

$$I(\alpha) = \oint_{|z|=1} z^\alpha dz \quad (4)$$

along the circle of radius $|z| = 1$, where $\alpha \in \mathbb{R}$.

This integral is computed as follows:

$$\begin{aligned} I(\alpha) &= \int_0^{2\pi} e^{i\alpha\theta} (ie^{i\theta}) d\theta = \int_0^{2\pi} e^{i(\alpha+1)\theta} d\theta \\ &= \frac{1}{i(\alpha+1)} \left[e^{i(\alpha+1)2\pi} - 1 \right] = \frac{e^{2\pi i\alpha} - 1}{i(\alpha+1)}. \end{aligned} \quad (5)$$

Notice that, as found in class, if $\alpha = 0, 1, \pm 2, \pm 3, \dots$, the result is identically zero. If $\alpha = -1$, then $I(\alpha) = 2\pi i$.

Now, let us restrict our attention to non-integer α . Upon first sight, it seems that the $I(\alpha) \equiv 0$ for such α , but upon closer inspection, one notices that the function z^α is multi-valued. Thus, z^α is not analytic for $\alpha \notin \mathbb{Z}$, and we must enforce some branch cut when defining z^α such that it is single-valued. Indeed, though, $I(\alpha)$ takes on different values

for different choices of branch cut. For example, in the computation above, we implicitly chose the branch cut along the real, positive axis. If we chose, however, the branch cut along the real, negative axis such that $\theta \in [-\pi, \pi)$, then

$$I(\alpha) = \frac{e^{i\pi\alpha} - e^{-i\pi\alpha}}{i(\alpha + 1)} = \frac{2}{\alpha + 1} \sin \pi\alpha. \quad (6)$$

Problem 3)

Calculate the integral

$$I = \oint_C \frac{z+1}{z^2+4} dz \text{ if :} \quad (7)$$

- (a) The point $2i$ is inside the contour C , and the point $-2i$ is outside the contour C .
- (b) The point $-2i$ is inside the contour C , and the point $2i$ is outside the contour C .
- (c) Both points $2i$ and $-2i$ are inside the contour C .

Observe that we can write

$$f(z) = \frac{z+1}{z^2+4} = \frac{z+1}{(z-2i)(z+2i)}, \quad (8)$$

which has poles at $\pm 2i$, and according to Cauchy's integral theorem

- (a) if C encloses the pole at $2i$ but not that at $-2i$, then

$$I = \frac{1}{2\pi i} \left[\frac{z+1}{z+2i} \right]_{z=2i} = \frac{1+2i}{8\pi}. \quad (9)$$

- (b) On the other hand, if C encloses the pole at $-2i$ but not that at $2i$, then

$$I = \frac{1}{2\pi i} \left[\frac{z+1}{z-2i} \right]_{z=-2i} = -\frac{1-2i}{8\pi}. \quad (10)$$

- (c) Now, if C encloses both poles, the result is just the sum of the previous two:

$$I = \frac{1+2i}{8\pi} - \frac{1-2i}{8\pi} = \frac{1}{4}i. \quad (11)$$

This fact can be seen easily. In our derivation of Cauchy's integral theorem, we only worried about a function with one simple pole, which we handled by “removing” it from

the integration region. For a function with n poles enclosed by C , we just repeat the argument at each pole, “removing” each of them individually, which gives us

$$\sum_{k=1}^n \phi_k(z_k) = \frac{1}{2\pi i} \int_C f(z) dz, \quad (12)$$

where $\phi_k(z) = (z - z_k)f(z)$. Alternatively, and more concretely, we could handle this particular case by writing $C = C_+ + C_-$, where C_{\pm} encloses only the pole at $z = \pm 2i$.

Problem 4)

The function defined by the series

$$I_4(z) = \frac{1}{1+z^2} = 1 - z^2 + z^4 - z^6 + \dots = \sum_{n=0}^{\infty} (-1)^n z^{2n} \quad (13)$$

is convergent at $|z| < 1$. Find the convergent series which analytically continues this function into the region $|z| > 1$.

Notice

$$\begin{aligned} I_4(z) &= \frac{1}{z^2} \frac{1}{1 - (-z^{-2})} = \frac{1}{z^2} \left[1 - \frac{1}{z^2} + \frac{1}{z^4} - \frac{1}{z^6} + \dots \right] \\ &= \frac{1}{z^2} - \frac{1}{z^4} + \frac{1}{z^6} - \frac{1}{z^8} + \dots, \end{aligned} \quad (14)$$

which is valid for $|1/z^2| > 1$ or $|z| > 1$.

Problem 5)

Expand the following function in the Laurent series in the neighborhood of $z = \infty$:

$$I_5(z) = \ln \frac{z^2 - a^2}{z^2 - b^2}. \quad (15)$$

Let us make the spatial inversion $t = 1/z$ ¹, which allows us to write

$$I_5(z) = \ln \left(\frac{1 - t^2 a^2}{1 - t^2 b^2} \right) = \ln(1 - t^2 a^2) - \ln(1 - t^2 b^2), \quad (16)$$

¹This allows us to expand $I_5(1/t)$ about $t = 0$, which is by construction an expansion of z in the neighborhood of ∞ .

and since $\ln(1+x) = x - x^2/2 + x^3/3 - x^4/4 \dots$, we have

$$\begin{aligned}
 I_5(z) &= \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (-t^2 a^2)^n - \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (-t^2 b^2)^n \\
 &= \sum_{n=1}^{\infty} \frac{1}{n} \frac{b^{2n} - a^{2n}}{z^{2n}} \\
 &= \frac{b^2 - a^2}{z^2} + \frac{b^4 - a^4}{z^4} + \frac{b^6 - a^6}{z^6} + \dots,
 \end{aligned} \tag{17}$$

where in the second-to-last line, we have replaced t with z to make the expansion in z explicit.

Problem 6)

Expand the following function in the Laurent series at $z = 0$:

$$I_6(z) = z^3 \exp\left(-\frac{1}{z^2}\right). \tag{18}$$

This can be done as follows:

$$\begin{aligned}
 I_6(z) &= z^3 \sum_{n=0}^{\infty} \frac{1}{n!} \left(-\frac{1}{z^2}\right)^n = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \frac{1}{z^{2n-3}} \\
 &= z^3 - z + \frac{1}{2z} - \frac{1}{6z^3} + \dots
 \end{aligned} \tag{19}$$
